Task 6 - Read and Print Data Correctly

C Programming Assignment - Rural Electricity Billing System

Input

For robust input, use fgets to read a line and strtoull or strtoll with errno and end-pointer checks. If using scanf, check its return value before using the variables.

Format specifiers

%d for int; %u for unsigned int; %ld for long; %lld for long long; %f for float in printf; %f for float pointer in scanf; %lf for double pointer in scanf; %c for char; %s for string. Use PRIu64 and PRId64 from inttypes.h for fixed-width integers.

Common error

A mismatched format specifier can cause undefined behavior. printf uses %f for double because float arguments are promoted. scanf uses %f for float pointer and %lf for double pointer.

Print money

For a non-negative paise amount p, print rupees and paise separately: printf with rupees p/100 and paise p%100, with two digits after the decimal.

Input comparison

fgets allows line validation; scanf is convenient but must be checked; sscanf parses a string; strtol and strtoll provide range and format error handling.

Important: illustrative tariff rates are used because the screenshot does not show the complete official tariff table. Replace them with your instructor's prescribed rates.
